The NIH now knows that the COVID vaccines can cause death 1 year from the vaccination date

A 61-year-old man got 1 dose of a COVID vaccine and developed severe neuropathy within days. The neuropathy continued for a year until he died of a stroke and massive blood clots. The NIH knows.

Just as a matter of public record, I wanted to point out that Dr. Avindra Nath, who was taking care of the vaccine injured at NIH, now knows of a vaccine-injured man who died a year after a single dose of COVID vaccine. The coroner confirmed the vaccine caused the death. This man was perfectly healthy before the vaccine and his health changed just days later with

symptoms consistent with vaccine injured. The blood clots in the autopsy are unique to COVID vaccine recipients and not seen in prior years.

Will the NIH alert the public of this? Of course not. The NIH still hasn't acknowledged that vaccine-injured people exist. Admitting that they know of a vaccine-injured man who died a year after a single shot would be a stretch for them.

But just because they won't admit it, it doesn't stop me from letting you know that they know.

The bottom line is this: the "death window" for the vaccine isn't days or weeks; it's **at least a year and possibly more**. So just because you got your vaccine and are still alive 3 months later, it does not mean that you're out of the woods.

Does anyone know of anyone who died from the vaccine more than a year from vaccination?

I just lost my 24yo cousin, a very athletic and active young man. He had a massive heart attack a week after getting the Pfizer jab. My aunt came down with Herpes Varicella Zoster, the worst kind, and they told her it was 'just a rash' with blisters and sores all over her body - 2 weeks after getting the Pfizer jab. No jabs for me, none. They can stick their jab in their azz.

My husband's aunt bled for 7 days after her shot, like a period. She's been in menopause for over 20 years.
